STREAMING HEALTH INVESTIGATION REPORT

**Subject:** Live Broadcast Telemetry Analysis & Root Cause Correction (Stream: `main-broadcast`) **Recipient:** Studio Head / Executive Producer **Status:** Major Broadcast Degradation (Intermittent Sequential Regional Spikes)

**What happened:**

During the high-profile live stream of `premiere-livestream` (stream: `main-broadcast`), viewers across multiple regions experienced severe playback interruptions, screen freezes (buffering), and stream errors. Initial monitoring notes and an automated dashboard annotation (Annotation ID 2) originally flagged a severe buffering incident in the West region at 09:22:20 UTC as a "CDN or edge delivery issue" because standard-resolution graphs showed origin CPU and transcoding latency were supposedly normal. However, by conducting a **high-resolution telemetry correlation** (running queries at fine-grained 10-second intervals), we have **disproved the CDN/edge theory**. We discovered that the transcoding pipeline suffered extreme but very brief, sub-minute overloads. Standard 60-second and 120-second graphs completely missed these spikes due to a phenomenon called **telemetry aliasing** (where the coarse sampling happened to land exactly before and after the transient spike), creating a false illusion that the origin was healthy when it was actually under severe stress.

**Root cause:**

The true root cause is **recurring, transient CPU starvation and overloading of the shared transcoding pipeline** (`streamguard-broadcast`).
